Optimizing Gaussian Processes

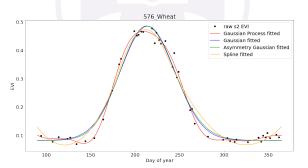

Honours Research Project

Michael Ciccotosto-Camp - 44302913

Problem Setting and Motivation

- This project focuses on the problem of time series prediction.
- Given a data set of n observations $\mathcal{D} = \{(x_i, y_i)\}_{i=1}^n$, where each input $x_i \in \mathbb{R}_{>0}$ is a time value and $y_i \in \mathbb{R}$ is a output or experimental observation that acts a function of time, the goal of time series prediction is to try and best predict a value y_* at time x_* .
- The idea of studying time series prediction came from a research group from the Gatton campus, lead by Andries Potgieter, analysing crop growth from previous seasons to forecast when certain phenological stages will take place in the current harvest.

Michael Ciccotosto-Camp Optimizing Gaussian Processes 2 / 9

Introduction to Gaussian Processes

- Originally, Potgieter's team surveyed a number of different parameteric models to carry out forecasting. However, the parameteric models we serverely limited in their ability to inform when key phenological stages would take place. After seeing the success of applying GPs to other remote senesing tasks investigated the use of GPs in their own research to find that they could produce much higher resolution predictions from which they could infer a far richer phenological timeline.
- A Gaussian Process (GP) is a collection of random variables with index set *I*, such that every finite subset of random variables has a joint Gaussian distribution.
- ullet A GP is completely characterized by a mean function $m:X o\mathbb{R}$ and a kernel $k:X imes X o\mathbb{R}$

$$m(\mathbf{x}) = \mathbb{E}[f(\mathbf{x})]$$

$$k(\mathbf{x}, \mathbf{x}') = \mathbb{E}[f(\mathbf{x}) - m(\mathbf{x}))(f(\mathbf{x}') - m(\mathbf{x}'))].$$

• In this context, think of the kernel as a function that provides some notion of similarity between points.

Predictions

- The aim of GPs is to find a suitable mean function, m, for which we can then predict inputs from outside the observed values, X_{\star} . This requires an understand of the function f.
- Adopting the notation $(\mathbf{K}_{WW'})_{i,j} \triangleq k(\mathbf{w}_i, \mathbf{w}_j')$, when attempting to model our value function we usually do not have access to the value function itself but a noisy version thereof, $y = f(\mathbf{x}) + \varepsilon$ where $\varepsilon \sim \mathbb{N}(0, \sigma_n^2)$ meaning the prior on the noisy values becomes $\text{cov}(\mathbf{y}) = \mathbf{K}\mathbf{x}\mathbf{x} + \sigma_n^2\mathbf{I}$.
- Using the assumption that our data can be modelled as a Gaussian process, we can
 write out the new distribution of the observed noisy values along the points at which
 we wish to test the underlying function as

$$\begin{bmatrix} \mathbf{y} \\ \mathbf{f}_{\star} \end{bmatrix} \sim \mathbb{N} \begin{pmatrix} \mathbf{0}, & \begin{bmatrix} \mathbf{K}_{\mathbf{X}\mathbf{X}} + \sigma_{n}^{2} \mathbb{I}_{n \times n} & \mathbf{K}_{\mathbf{X}_{\star} \mathbf{X}}^{\mathsf{T}} \\ \mathbf{K}_{\mathbf{X}_{\star} \mathbf{X}} & \mathbf{K}_{\mathbf{X}_{\star} \mathbf{X}_{\star}} \end{bmatrix} \end{pmatrix}.$$

• The mean and covariance can then be computed as

$$\begin{aligned} \overline{\boldsymbol{f}_{\star}} &\triangleq \boldsymbol{K}_{\boldsymbol{X}_{\star}\boldsymbol{X}} \left[\boldsymbol{K}_{\boldsymbol{X}\boldsymbol{X}} + \sigma_{n}^{2} \mathbb{I}_{n \times n} \right]^{-1} \boldsymbol{y} \\ \operatorname{cov}(\boldsymbol{f}_{\star}) &= \boldsymbol{K}_{\boldsymbol{X}_{\star}\boldsymbol{X}_{\star}} - \boldsymbol{K}_{\boldsymbol{X}_{\star}\boldsymbol{X}} \left[\boldsymbol{K}_{\boldsymbol{X}\boldsymbol{X}} + \sigma_{n}^{2} \mathbb{I}_{n \times n} \right]^{-1} \boldsymbol{K}_{\boldsymbol{X}_{\star}\boldsymbol{X}}^{\mathsf{T}}. \end{aligned}$$

Unoptimized GPR

Algorithm 1: Unoptimized GPR

input: Observations X, y and a test input x_{\star} . **output**: A prediction $\overline{f_{\star}}$ with its corresponding variance $\mathbb{V}[f_{\star}]$.

1
$$m{L} = \mathsf{cholesky}\left(m{K}_{m{X}m{X}} + \sigma_n^2 \mathbb{I}_{n imes n} \right)$$

2
$$\alpha = \text{lin-solve}(\hat{\boldsymbol{L}}^{\intercal}, \text{lin-solve}(\hat{\boldsymbol{L}}, \boldsymbol{y}))$$

з
$$\overline{f_\star} = \pmb{K}_{\pmb{x_\star} \pmb{X}} \pmb{\alpha}$$

4
$$\mathbf{v} = \text{lin-solve}(\mathbf{L}, \mathbf{K}_{x_{\star} \mathbf{X}})$$

$$\mathsf{S} \ \mathbb{V}[f_{\star}] = \mathbf{K}_{\mathbf{x}_{\star} \mathbf{x}_{\star}} - \mathbf{v}^{\mathsf{T}} \mathbf{v}$$

6 return $\overline{f_{\star}}, \mathbb{V}\left[f_{\star}\right]$

Problems with Unoptimized GPR

Algorithm 2: Unoptimized GPR

input: Observations X, y and a test input x_{\star} . output: A prediction $\overline{f_{\star}}$ with its corresponding variance $\mathbb{V}[f_{\star}]$.

- 1 $L = \text{cholesky} \left(K_{XX} + \sigma_n^2 \mathbb{I}_{n \times n} \right)$
- 2 $\alpha = \text{lin-solve}(\boldsymbol{L}^{\mathsf{T}}, \text{lin-solve}(\boldsymbol{L}, \boldsymbol{y}))$
- $\overline{f_{\star}} = K_{x_{\star}X}\alpha$
- 4 $\mathbf{v} = \text{lin-solve}(\mathbf{L}, \mathbf{K}_{x_{\star} \mathbf{X}})$
- $\mathbf{v}[f_{\star}] = \mathbf{K}_{\mathbf{x}_{\star}\mathbf{x}_{\star}} \mathbf{v}^{\mathsf{T}}\mathbf{v}$
- 6 return $\overline{f_{\star}}$, $\mathbb{V}[f_{\star}]$
- Line 1 can be incredibly slow as computing K_{XX} and performing a Cholesky decomposition scale poorly as the number of inputs, n, grows.

Nystrom Approximation

- One technique to speed up the computation of K_{XX} is to use a Nystrom approximation.
- The Nystrom method we seek a matrix $Q \in \mathbb{R}^{n \times k}$ that satisfies $\|A QQ^*A\|_F \leq \varepsilon$, where $A \in \mathbb{R}^{n \times n}$ is positive semi definite matrix, to form the rank-k approximation

$$egin{aligned} oldsymbol{A} &\simeq oldsymbol{Q} oldsymbol{Q}^* \ &\simeq oldsymbol{Q} \left(oldsymbol{Q}^* oldsymbol{A} oldsymbol{Q}
ight) oldsymbol{Q}^* oldsymbol{A} oldsymbol{Q} \left(oldsymbol{Q}^* oldsymbol{A} oldsymbol{Q}
ight)^\dagger \left(oldsymbol{Q}^* oldsymbol{A} oldsymbol{Q}
ight)^\dagger \left(oldsymbol{Q}^* oldsymbol{A} oldsymbol{Q}
ight). \end{aligned}$$

- ullet A matrix $oldsymbol{Q}$ that satisfies the above conditions can be built using through a very popular column sampling technique.
- As the name suggests, the matrix Q essentially samples and rescales columns from A using a probability distribution $\{p_i\}_{i=1}^n$.
- ullet When $oldsymbol{Q}$ is constructed in this manner, it is usually referred to as a sketching matrix and denoted $oldsymbol{S}$

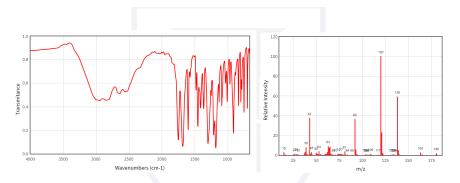

Random Fourier Feature Approximation

- The other technique investigated to speed up the computation of K_{XX} is the Random Fourier Feature (RFF) approximation.
- The main idea is instead of using a kernel function to implicitly lift data into a higher dimensional feature space, an explicit feature map $\varphi: \mathbb{R}^d \to \mathbb{R}^D$ could be used to approximate k as $k(\mathbf{x}, \mathbf{y}) = \langle \Phi(\mathbf{x}), \Phi(\mathbf{y}) \rangle_{\mathbb{R}^N} \simeq \langle \varphi(\mathbf{x}), \varphi(\mathbf{y}) \rangle_{\mathbb{R}^D}$ where D is chosen so that $n \gg D$. Once $\varphi(\mathbf{x}_i)$ has been computed for each \mathbf{x}_i , every entry of the Gram matrix can be swiftly approximated as $\mathbf{K}_{ij} = \mathbf{K}_{ji} \simeq \langle \varphi(\mathbf{x}_i), \varphi(\mathbf{y}_i) \rangle_{\mathbb{R}^D}$.
- The RFF technique hinges on Bochners theorem which characterises positive definite functions (namely kernels) and states that any positive definite functions can be represented as

$$k(\mathbf{x} - \mathbf{y}) = k(\mathbf{x} - \mathbf{y}) = \int_{\mathbb{C}^d} \exp(i\langle \omega, \mathbf{x} - \mathbf{y} \rangle) \mu_k(d\omega)$$

where μ_k is a positive finite measure on the frequencies of ω .

Infrared Spectroscopy and Mass Spectrum Data

 Project Goal: Develop a deep learning model to accurately predict functional groups based off Infrared (IR) and Mass Spectrometry (MS) data¹. Main focus will be on Multi-layer Perceptrons (MLPs).
